MDF and .ndf SQL database files as well as .accdb SQL database files that might have been deleted. Computer spyware is a form of spyware, adware, and other non-security software bundled together with a popular legitimate software product by a third-party developer (or publisher). These trojans and adware may be bundled with several free software applications available for download on the Internet. Computer spyware typically includes unwanted and potentially unwanted programs, as well as some commercial malware that is of little or no value to the user but may interfere with legitimate software. Computer spyware

is often included by the developers of the software that it modifies or replaces.[1][2] Spyware should not be confused with adware, which is often bundled with products without the user's consent. However, they often complement each other. Spyware is able to secretly monitor the activities of the computer. Spyware usually produces no popup advertisements. Cyber attacks such as virus infections and worms often gain access to the computer through a USB or network port, resulting in the infection of the installed software. Anti-virus software is an important component of a successful security system. However, because it is designed to protect against known threats, it may not be able to detect or remove a variety of threats, including spyware. Some types of spyware, such as the monitor programs included with software bundles, can provide useful information for the program's developer. Additionally, a software provider may wish to use the information in order to deliver updates, or advertisements. Most modern computer systems are vulnerable to infection. Commonly, infected computers are sometimes used to carry out cyber crime, such as Distributed Denial of Service (DDoS) attacks, fraudulent transactions, identity theft, and the trafficking of illegal content. Spyware can give the user a false sense of security; the user thinks that his or her system is secure and considers the possibility of spyware to be extremely low, when in fact it is far from being the case. To illustrate the problem, in late 2008, anti-virus software began detecting an outbreak of the worm known as Conficker, which had been spreading through network-infected PCs in large numbers. As a result, many people who believed their system to be safe experienced frustration and surprise when the anti-virus software warned them that their system was infected. Though many anti-spyware software programs exist, few are capable of completely eliminating 82157476af
